11 Introduction

12 Benchmark for Nature is a project at the University of Oxford's Internet Institute, emerging from the
13 global movement towards sustainable business. The project aims to use data science to develop a
14 framework for assessing investment impacts on biodiversity [ICCS, 2020], similar to the ESG frame-
15 work currently in place. The ESG information currently available only assesses an investments'
16 impact on the environment, but not on living nature and biodiversity. The purpose of the project
17 is to better inform investors so that more biodiversity-conscious decisions can be made, in an effort
18 to aid the biodiversity loss crisis [Gasu et al., 2021], and also indirectly, the climate [Shin et al., 2022].

19

20 Many indicators have been determined within the project as definitions of how biodiversity impact
21 will be assessed. One question that has been raised is whether these indicators have equal impacts
22 on biodiversity regardless of geography, as is a current assumption. Studies show impacts of socioe-
23 conomic status and cultural impacts on biodiversity [Kinzig et al., 2005]. This gives reason to believe
24 that contributors towards biodiversity loss could have varying impacts based on their location. For ex-
25 ample, this research question would aim to provide answers for whether investing in a specific sector
26 in one country could have a different impact on biodiversity than investing in the same sector in an-
27 other country. I will aim to address this question and determine any association between geography
28 and the level of biodiversity impact of a company.

29 Methods

30 Benchmark for nature is working on open-source data from news articles that have been scraped
31 over the past few years. Therefore my project involves no data collection, and I will be working with
32 data that is already available.

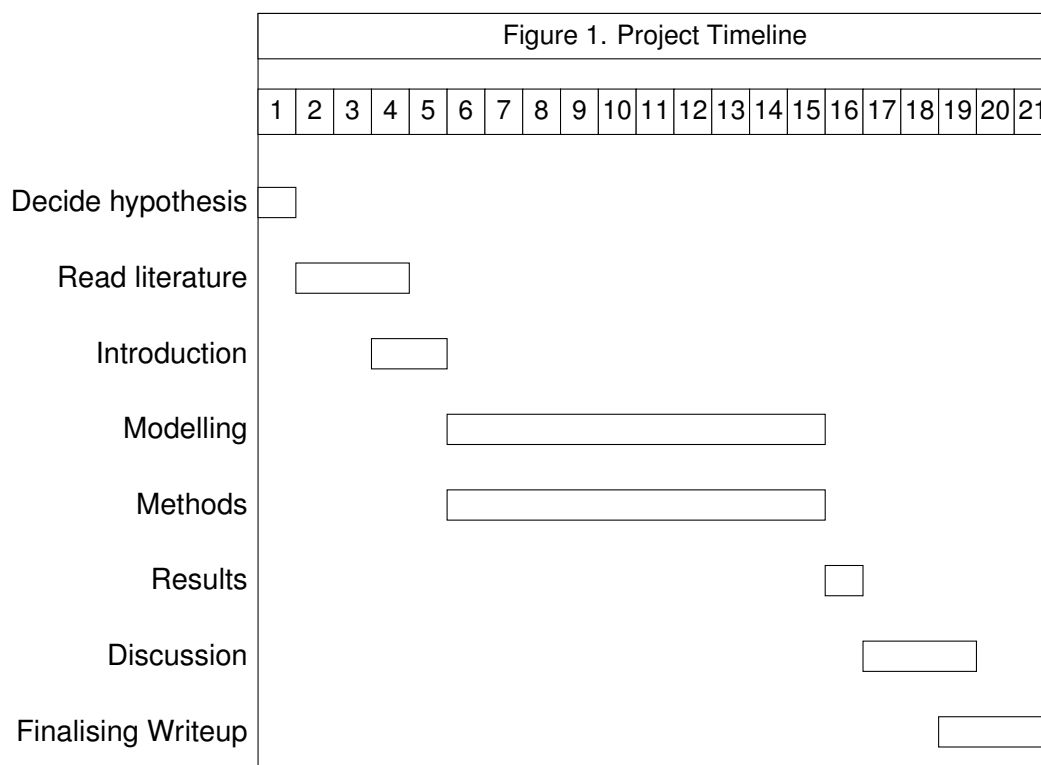

33

34 My project will involve pulling out geographical elements from this data and devising a method that
35 can assess how impacts change based on country. It is important to note that the research ques-
36 tion is not about the impact of country on biodiversity, but rather if country can affect the scale of a
37 sector's impact on biodiversity. I will use a generalised linear model, with country as an explanatory
38 variable. The response variable will be specified upon further inspection of the data but will roughly
39 be associated with how often a sector in that country is associated with indicators of biodiversity loss.

40 Outcomes

41 The main stakeholder in my project is the Benchmark for Nature team, who are interested in the
 42 answer to the question I am raising. There has been no work done as of yet within the project to
 43 determine geographical differences, therefore the outcome of my project will aid the researchers on
 44 the project in their research into geographical effects of investments on biodiversity.

45 Figure 1 shows a timeline of the projects' progress

47 Feasibility

48 This project is very feasible, given that the data has already been collected and the question has
 49 many gradations of success.

50 There is no data collection involved, therefore no funding is needed for field or lab work. There may
 51 be small costs involved for software access, given that this is a desk based project.
